Study of Standard Materials for the Correction of Low-frequency Raman Spectra

Tatsuo KOIDE^{*1}, Ayumi SAITO^{*2}, Atsuto KONDO^{*2} and Toshiro FUKAMI^{*2}

Summary

The purpose of this study was to investigate standard materials for the correction of low-frequency Raman spectra. We selected five compounds, sulfur, acetaminophen, L-cystine, cyclohexane and polystyrene, as candidate reference standard materials, and measured their low-frequency Raman spectra. Several peaks were confirmed in the spectra of crystalline compounds (sulfur, acetaminophen and L-cystine), while no peak was observed in the spectra of non-crystalline compounds (cyclohexane and polystyrene). Thus, non-crystalline compounds are not suitable as standard materials. Acetaminophen showed different Raman spectra in the low-frequency region depending upon its polymorphic form and crystal habit. Therefore, it is important to choose a stable crystalline form as a standard material, and to ensure that the material shows a consistent crystal habit, in order to obtain consistent standard Raman spectra.
